

ABSTRACT OF THE DISCLOSURE

A system is provided for dynamically converting non-voice enabled documents into voice enabled pages written in VoiceXML without the need for manually coding the document into VoiceXML. The system includes a voice server for accepting the original document, a data server for accepting said HTML document; a run time engine for applying an XSLT translator to such HTML document as well as any requisite data information rendering a VoiceXML version of the original document without the need to manually code such document. It will be appreciated that the system can be used to dynamically convert other non-voice enabled documents.
